Texas Hospital Quality Data Cleaning Changelog

- 09-17-26:
 - I used Power Query to import Hospital_General_Information.csv into cms-tx-hospital-quality-excel.xlsx. I created a query that retains relevant columns, stores identifiers as text, trims text, filters state = TX and acute care hospitals, converts valid ratings, preserves raw rating, and preserves footnote on the raw file and outputs the cleaned file to worksheet hospital-cleaned.
 - I created the QA_Hospital_Duplicates query to check for duplicates, which resulted in none.
- 09-18-26:
 - I used Power Query to import HCA-HPS-Hospital.csv into the excel worksheet. Then I filtered the data to Texas hospitals.
 - I changed the grain to long view, keeping only these measures H_COMP_1_A_P (Nurses always communicated well), H_COMP_2_A_P (Doctors always communicated well), H_COMP_5_A_P (Staff always explained medicines), H_COMP_6_Y_P (Patients received recovery information), H_HSP_RATING_9_10 (Patients rated the hospital 9 or 10), and H_RECMND_DY (Patients would definitely recommend the hospital). The resulting grain was one row per Facility_ID and HCAHPS Measure ID.
 - I converted these text data type columns into the correct data type: Numeric Answer Percent, Numeric Response Rate, Start Date, End Date.
 - I retained only eligible hospitals that were also present in the cleaned hospital table and standardized the column names.
 - I created the QA_HCAHPS_Duplicates query to check for duplicates.
 - I created the QA_HCAHPS_Metadata_Inconsistencies query to identify cases where records with the same Facility_ID contained conflicting descriptive information, such as different hospital names or location details.
 - I created the HCAHPS_Clean query to prepare patient experience data for analysis. I filtered records to Texas and selected patient experience measures, converted percentage and reporting period fields into usable numeric and date formats. Non-numeric or unavailable values were retained as nulls rather than replaced with zero. The query then kept only hospitals included in the cleaned acute care hospital list, removed the temporary

merge columns, and then standardized the facility ID field name for later analysis and joins. The grain became one row per hospital with at least one selected HCAHPS record.

- 09-19-26:
 - I imported `Unplanned_Hospital_Visits-Hospital.csv` using the `Unplanned_Raw` query.
 - In the `Readmission_Selected_Long` query, I filtered unplanned hospital visits table to the `Hybrid_HWR` hospital wide readmission measurement, and retained the denominator, risk standardized score, estimates, and national comparison fields used to interpret readmission performance. Number of Patients and Number of Patients Return fields all say “Non-Applicable” because CMS does not use those two particular output columns to publish patient return counts for `Hybrid_HWR`.
 - In the `QA_Readmission_Duplicates` query, I checked for duplicates and found none.
 - In the `Readmission_Clean` query, I cleaned the query to keep only the fields I needed, then renamed a column for consistency.
 - I formatted the appropriate columns as percentage point values.
- 09-20-2026:
 - I created the `Analysis_Model` query to build the final hospital level analysis table. `Hospital_Clean` was used as the base table. I used left outer joins on `Facility_ID` to bring in matching records from the cleaned HCAHPS and readmission tables while preserving all in scope hospitals.
 - I created the `QA_Hospitals_Without_HCAHPS` query to identify hospitals in `Hospital_Clean` without selected HCAHPS data.
 - I created the `QA_Hospitals_Without_Readmission` query to identify hospitals in `Hospital_Clean` without selected readmission data.
 - I created the `QA_Model_Summary` query to provide a small set of record counts used to validate that the final analytical model appeared reasonable.
 - I used Power Query data profiling in order to validate that field lengths, percentages, reporting periods, and categorical fields were correct. Then I performed manual spot checks for at least five hospitals, one with a high overall rating, one with a low overall rating, one with an unavailable overall rating, one with completed HCHPS and readmission results, and one missing either HCHPS or readmission rate results to compare their fields to make sure they matched.

- I refreshed all queries to confirm there were no errors, then did a second refresh after reopening the workbook to verify it is not relying on temporary query preview information.
